7. Unless otherwise stated, the figures in this chapter were photographed by Bruce and Kenneth Zuckerman in collaboration with the Princeton Theological Seminary. Courtesy Department of Antiquities, Amman. Imaging by Marilyn Lundberg.

to build composite photographs, apparently by cutting up prints and rephotographing the prints in their composite form. Computer imaging enables such composites to be built with a great deal more precision so that a 'flattened' cut can be displayed on screen, written onto film and published (Fig. 4.5[a]-[d]). Here the flattest areas from four rotations of Cut 15, col. 8 have been selected and moved to create a simulation of the section before it was rolled (cf. Fig. 4.1). The same can be done with separate cuts to complete whole columns of text (Fig. 4.6). In this case, composites were made of Cuts 5 and 6 (col. 2) and then joined together to create an entire column. The joins between cuts, of course, are more visible, due to the deterioration over time of the edges of the cuts.

(4) The convention of drawing becomes easier on a computer screen because computer programs such as Adobe Photoshop offer powerful tools that can turn any trained epigrapher into a superior graphic artist. A series of points can be placed along a given letter (Fig. 4.7). The computer joins, or draws, between the points, which can be precisely adjusted at high magnification. One need not be very good at drawing to produce precision drawing accurate to a scale of microns. In addition, the ability to draw right on the text allows for a very high degree of accuracy (Fig. 4.8).
